

Solutions to sample questions for CS111 Midterm Exam 1.

Problem 1: Buggle World Execution

Consider the two Java classes in Fig. 1.

```
public class DoItWorld extends BuggleWorld
{
    public void run ()
    {
        DoItBuggle dewey = new DoItBuggle();    // run statement 1
        int n = 5;                               // run statement 2
        dewey.setPosition(new Point(n,n-2));     // run statement 3 *
        dewey.brushUp();                          // run statement 4
        dewey.doit(Color.green, n-1);            // run statement 5 *
        dewey.doit(Color.blue, n+1);            // run statement 6 *
        dewey.forward();                         // run statement 7
        dewey.brushDown();                      // run statement 8
        dewey.forward(3);                       // run statement 9 *
    }
}

class DoItBuggle extends Buggle
{
    public void doit (Color c, int n)
    {
        Color oldColor = this.getColor();
        this.setColor(c);
        this.forward(n);
        this.brushDown();
        this.backward(n-2);
        this.brushUp();
        this.backward(2);
        this.left();
        this.setColor(oldColor);
    }
}
```

Figure 1: Two Java classes.

Suppose that the `run()` method is invoked on an instance of `DoItWorld` which has a 10×10 grid of cells. In the four grids on the following page, show the state of the grid directly *after* the execution of each of the statements in the `run()` method body marked with a `*`.

In each grid, you should show the following:

1. Draw buggle **dewey** as a triangle “pointing” in the direction that the buggle is facing.
2. Indicate the current color of the buggle by putting the *first letter* of the color name inside the triangle (e.g. **B** for blue, **G** for green, etc.).
3. Indicate the color of each non-white grid cell by putting the *first letter* of the color name inside the cell (e.g. **B** for blue, **G** for green, etc.).

DoItWorld grid after the
execution of `run()` statement 3

DoItWorld grid after the
execution of `run()` statement 5

DoItWorld grid after the
execution of `run()` statement 6

DoItWorld grid after the
execution of `run()` statement 9

Problem 2: Writing Methods

Suppose that `LetterWorld` is a subclass of `PictureWorld` that supplies you with a method named `f()` with the following contract:

```
public Picture f (Color c)
```

Returns a picture of the letter “F” in color `c`, as shown below.

The dotted lines indicate the boundaries of the unit square, and are *not* part of the picture. The letter is a solid color `c` and does *not* have any boundary line drawn in a separate color.

On the next page your task is to write *two* methods:

1. A method named `e()` that takes a single color parameter and returns the following picture of the letter “E” in that color.

2. A method named `fame()` that takes two color parameters and returns the following picture:

The “F” and “E” have the color of the first parameter, while the “A” and “M” have the color of the second parameter.

You may assume that both methods are defined in the `LetterWorld` class, and so may use the `f()` method in addition to the methods in the `PictureWorld` contract (e.g., `clockwise90()`, `flipDiagonally()`, `above()`, etc.). You may assume that the `fourPics()` and `fourSame()` methods defined in class and on the problem sets are also available. Your `fame()` method may use your `e()` method, which you may assume works correctly (even if your definition of `e()` is actually incorrect or missing).

Put your definition of the e() method here.

Here is a solution that does not name any intermediate pictures:

```
// The letter "E" can be formed by overlaying an "F"
// and a copy of "F" flipped across the horizontal axis.
public Picture e (Color c)
{
    return overlay(f(c), flipHorizontally(f(c)));
}
```

Here is another solution, which names some intermediate pictures:

```
public Picture e (Color c)
{
    Public picture f_c = f(c);
    Public picture f_c_flipH = flipHorizontally(f_c);
    return overlay(f_c, f_c_flipH);
}
```

Put your definition of the fame() method here.

Here is one solution, which does not name any intermediate pictures:

```
// Create a picture consisting of quadrants "F", "A", "M", "E"
// where "F" and "E" are in color c1 and "A" and "M" are in color c2
public Picture fame (Color c1, Color c2)
{
    return fourPics(f(c1), // F
        overlay(f(c2),
            flipVertically(f(c2))), // make A out of 2 Fs
        clockwise90(e(c2)), // M is rotated E
        e(c1)); // E
}
```

Here is another solution, which names some intermediate pictures:

```
public Picture fame (Color c1, Color c2)
{
    Picture f_c1 = f(c1);
    Picture f_c2 = f(c2);
    Picture a_c2 = overlay(f_c2, flipVertically(f_c2));
    Picture m_c2 = clockwise90(e(c2));
    Picture e_c1 = e(c1);
    return fourPics(f_c1, a_c2, m_c2, e_c1);
}
```

Problem 3: Debugging

The class declarations in Fig. 2 contain (at least) **10 errors** (syntax errors and type errors).

```
public class ExamBuggleWorld extends BuggleWorld    // line 1
{
    public void run ()                                // line 2
    {
        Color c = Color.cyan();                      // line 3
        int n = 4                                     // line 4
        ExamBuggle emma = ExamBuggle();              // line 5
        emma.mystery1(c,n);                          // line 6
        emma.mystery1(3,Color.red);                  // line 7
        boolean answer = emma.mystery2();             // line 8
        this.mystery3();                             // line 9
    }                                                  // line 10
}                                                     // line 11

class ExamBuggle extends Buggle                    // line 12
{
    public void mystery1(Color c, int n1)            // line 13
    {
        n2 = n1 + 1;                                // line 14
        this.setColor(Color.c);                     // line 15
        forward(n2);                                 // line 16
        this.dropBagel();                           // line 17
    }                                                  // line 18

    public boolean mystery2()                        // line 19
    {
        this.isOverBagel();                         // line 20
    }                                                  // line 21

    public mystery3()                                // line 22
    {
        this.dropBagel();                           // line 23
    }                                                  // line 24
}                                                     // line 25
```

Figure 2:

In the table on the next page, for each of 10 errors in different lines of the above program give:

1. the line number of the error,
2. a *brief* description of the error, and
3. a corrected version of the line (i.e., with the error fixed).

You may list the errors in *any* order. You do *not* have to list them in the order in which they occur in the program.

Error #	Line #	Brief description of error	Corrected line
1	5	<code>Color.cyan()</code> is not a method invocation	<code>Color c = Color.cyan;</code>
2	6	The local variable declaration <code>int n = 4</code> is missing a semi-colon at the end	<code>int n = 4;</code>
3	7	There is a missing <code>new</code> in the constructor method invocation that creates an <code>ExamBuggle</code>	<code>ExamBuggle emma = new ExamBuggle();</code>
4	9	The two arguments of the instance method invocation <code>emma.mystery1(3,Color.red)</code> are in the wrong order	<code>emma.mystery1(Color.red,3);</code>
5	11	In <code>this.mystery3()</code> , <code>this</code> stands for an instance of <code>ExamBuggleWorld</code> , which does not understand the <code>mystery3()</code> message; the recipient should be an instance of <code>ExamBuggle</code>	<code>emma.mystery3();</code>
6	19	The local variable declaration <code>n2 = n1 + 1;</code> is missing a type for the contents of the variable	<code>int n2 = n1 + 1;</code>
7	20	<code>Color.c</code> attempts to reference a non-existent class constant rather than the parameter <code>c</code>	<code>this.setColor(c);</code>
8	23	The instance method declaration for <code>mystery1()</code> is missing a close squiggly brace.	<code>}</code>
9	26	The non-void method <code>mystery2()</code> is missing a return statement.	<code>return this.isOverBagel();</code>
10	29	The method header for <code>mystery3()</code> is missing the return type, <code>void</code>	<code>public void mystery3()</code>
